# Triangle-Triangle Intersection Determination and Classification to Support Qualitative Spatial Reasoning 

Chaman L. Sabharwal, Jennifer L. Leopold, Douglas McGeehan

#### Abstract

In CAD/CAM modeling, objects are represented using the Boundary Representation (ANSI Brep) model. Detection of possible intersection between objects can be based on the objects' boundaries (i.e., triangulated surfaces), and computed using triangle-triangle intersection. Usually only a cross intersection algorithm is needed; however, it is beneficial to have a single robust and fast intersection detection algorithm for both cross and coplanar intersections. For qualitative spatial reasoning, a general-purpose algorithm is desirable for accurately differentiating the relations in a region connection calculus, a task that requires consideration of intersection between objects. Herein we present a complete uniform integrated algorithm for both cross and coplanar intersection. Additionally, we present parametric methods for classifying and computing intersection points. This work is applicable to most region connection calculi, particularly VRCC-3D+, which detects intersections between 3D objects as well as their projections in 2D that are essential for occlusion detection.

Index Terms-Intersection detection, classification predicates, spatial reasoning, triangle-triangle intersection.

## I. Introduction

THERE are relatively few software applications supporting qualitative spatial reasoning. In part, this may be due to the complexity in determining the intersection between 2D/3D objects. Yet the ability to detect the existence of a possible intersection between pairs of objects can be important in a variety of problem domains such as geographic information systems [1], CAD/CAM geometric modeling [2], real-time rendering [3], geology [4], networking and wireless computing.

In qualitative reasoning, it is not necessary to know the precise intersection between pairs of objects; it is sufficient to detect and classify the intersection between objects. Typically, the boundary of each object is represented as a triangulated surface and a triangle-triangle intersection is the computational basis for determining intersection between objects. Since an object boundary may contain thousands of

[^0]triangles, algorithms to speed up the intersection detection process are still being explored for various applications, sometimes with a focus on innovations in processor architecture [5, 6, 7].

For pairs of triangles, there are three types of intersections: zero dimensional (single point), one-dimensional (line segment), and two dimensional (area) intersection. In the past, almost all attention has been devoted to determining the cross intersections, which resulted in an absence of analysis in twodimensional intersections. Coplanar triangle intersections are unique because an intersection may be any of the aforementioned three types. If the triangles cross-intersect, only zero or one-dimensional intersection is possible. If the planes are parallel and distinct, the triangles do not intersect. If the triangles are coplanar, then there is a possibility of intersection. Even when the cost of intersecting a triangle pair is constant, the cost of intersecting a pair of objects A and B is order $O\left(\mathrm{~T}_{\mathrm{A}} \times \mathrm{T}_{\mathrm{B}}\right)$ where $\mathrm{T}_{\mathrm{A}}$ is the number of triangles in object $A$, and $T_{B}$ is the number of triangles in object $B$.

In qualitative spatial reasoning, spatial relations between regions are defined axiomatically using first order logic [8] or the 9 -Intersection model [9]. Using the latter model, the spatial relations are defined using the intersections of the interior, boundary, and exterior of one region with those of a second region. It has been shown in [10] that it is sufficient to define the spatial relations by computing 4-Intersection predicates, (namely, Interior-Interior (IntInt), BoundaryBoundary (BndBnd), Interior-Boundary (IntBnd), and Boundary-Interior (BndInt)) instead of 9-Intersections.

Since IntBnd and BndInt are the converse of each other, only three algorithms are necessary for these predicates. In order to implement these algorithms, we must first solve the triangle-triangle intersection determination, as it is a lower level problem that must be solved in order to determine the 4 Intersection predicates that, in turn, determine the qualitative spatial relation between two objects.

This paper is organized as follows: Section II briefly reviews the background and related cross intersection framework. Section III discusses motivation and conceptual classification of intersections, whereupon Section IV develops the overall main algorithm for triangle-triangle intersection. Section V describes the area intersection algorithm for general
triangles, and predicates for classifying the intersection between pairs of triangles, after which Section VI discusses the applications to qualitative spatial reasoning.

## II. BACKGROUND

## A. The Traditional Algorithm

Many papers have been written on the intersection between a pair of triangles [3, 11, 12, 13, 14, 15]. Interestingly, most of them simply reinvent the algorithm and implement it slightly differently and more efficiently, with no innovation. A recent paper [7] surveyed various approaches for determining the cross intersection detection, and developed a fast vector version of the cross intersection detection, as well as classification of the type of intersection. Our approach is exhaustive, integrating both cross and coplanar intersection, and analytically more rigorous than the previous approaches [3, 11]. It is described in the next section where we follow the approach similar to the techniques used in [7] for cross intersection. The cross-intersection standalone algorithm is described as follows:

## boolean triTriCrossInt (tr1 $=A B C, \operatorname{tr} 2=P Q R)$

input: two triangles whose planes cross intersect
output: true if the triangles intersect, else false
The vector equations for two triangles ABC and PQR are

$$
\begin{gathered}
R_{1}(u, v)=A+u U+v V, 0 \leq u, v, u+v \leq 1 \\
R_{2}(s, t)=P+s S+t T, 0 \leq s, t, s+t \leq 1
\end{gathered}
$$

where $U=B-A, V=C-A$, and $S=Q-P, T=R-P$.
Let $\mathrm{N}_{1}=\mathrm{U} \times \mathrm{V}, \mathrm{N}_{2}=\mathrm{S} \times \mathrm{T}$ be normals to the planes supporting the triangles directed away from the objects. The triangles intersect if there exist some barycentric coordinates $(\mathrm{u}, \mathrm{v})$ and $(\mathrm{s}, \mathrm{t})$ satisfying the equation

$$
A+u U+v V=P+s S+t T
$$

Since $\mathrm{N}_{1} \mathrm{xN}_{2} \neq 0$ for cross intersecting triangles, and S and T are orthogonal to $\mathrm{N}_{2}$, the dot product of this equation with $N_{2}$ eliminates $S$ and $T$ from the above equation to yield

$$
u U \cdot N_{2}+v V \bullet N_{2}=A P \cdot N_{2}
$$

This is the familiar equation of a line in the $u v$-plane for real variables $u$, $v$. The vector equation using real parameter $\lambda$ becomes

$$
(u, v)=A P \bullet N_{2} \frac{\left(U \bullet N_{2}, V \bullet N_{2}\right)}{U \bullet N_{2}{ }^{2}+V \bullet N_{2}{ }^{2}}+\lambda\left(V \bullet N_{2},-U \bullet N_{2}\right)
$$

Then parameter values $\mathrm{u}, \mathrm{v}$ are explicitly written as

$$
\begin{aligned}
& u=A P \bullet N_{2} \frac{U \bullet N_{2}}{U \bullet N_{2}^{2}+V \bullet N_{2}^{2}}+\lambda V \bullet N_{2} \\
& v=A P \bullet N_{2} \frac{V \bullet N_{2}}{U \bullet N_{2}^{2}+V \bullet N_{2}^{2}}-\lambda U \bullet N_{2} \\
& u+v=A P \bullet N_{2} \frac{\left(U \bullet N_{2}+V \bullet N_{2}\right)}{U \bullet N_{2}^{2}+V \bullet N_{2}^{2}}+\lambda\left(V \bullet N_{2}-U \bullet N_{2}\right)
\end{aligned}
$$

If there is a $\lambda$ in these three equations such that $0 \leq u, v, u$ $+\mathrm{v} \leq 1$, the triangles are ensured to intersect. The range of values of $\lambda$ is bounded by $\lambda_{\mathrm{m}}$ and $\lambda_{\mathrm{M}}$. This detects whether the two triangles cross intersect only.

In fact, for precise intersection, using $\lambda_{m}, \lambda_{M}$, as parameter values, we compute $\left(u_{m}, v_{m}\right)$ and $\left(u_{M}, v_{M}\right)$ for the segment of intersection on ABC. Similarly the values $\left(s_{m}, t_{m}\right)$ and $\left(s_{M}, t_{M}\right)$ represent the segment of intersection on PQR. The precise intersection between the two triangles is the common segment of these two segments. If the segment degenerates into a single point, the parameter values also can be used to classify the intersection as a vertex, an edgeInterior point or triangleInterior point in the triangle ABC .

## III. Classification of Triangle Intersections

For spatial reasoning, we detect intersection between pairs of $2 \mathrm{D} / 3 \mathrm{D}$ objects and classify pairwise intersection predicates IntInt, IntBnd, BndInt, and BndBnd, without computing the extent of intersections. The cross intersection can be characterized into seven categories [7]. When cross intersection is insufficient to determine tangential intersection, some applications such as RCC8 and VRCC-3D ${ }^{+}$[6] resort to coplanar intersection to support relations such as externally connected (EC) and tangentially connected (TPP, TPPc).

The precise intersection of coplanar triangles is a little more complex because it can result in area intersection as well; the coplanar triangles intersection can be classified as: Single Point Intersection (vertex-vertex, vertex-edgeInterior), Line Segment Intersection (edge-edgeCollinear), Area Intersection bounded by 3, 4, 5, 6 edges, (Fig. 4, Fig. 5(a, b, c)). A triangle may be entirely contained in the other triangle (Fig. 5(d)). In this paper, we present a detailed analytical study of the intersection of coplanar triangles, which has not been previously presented.
The intersection between a pair of triangles can be abstracted as Cross (C) intersection or Parallel (P) coplanar triangles intersection. For taxonomy of cross and parallel coplanar triangles, the conceptual intersections are supported with figures presented here. The specific cases are as follows:

## No intersection

disjoint (C, P) (see Fig. 1)

## Single Point Intersection

vertex-vertex Intersection (C, P) (see Fig. 2(a))
vertex-edgeInterior Intersection (C, P) (see Fig. 2(b))
vertex-triangleInterior Intersection (C) (see Fig. 2(c)) edgeInterior-edgeInteriorCross Intersection (C) (Fig. 2(d))

## Line intersection

edge-edgeCollinear Intersection (C, P) (see Fig. 3(a))
edge-triangleInterior Intersection (C) (see Fig. 3(b))
triangleInterior-triangleInterior Intersection (C) (Fig. 3(c))

## Area Intersection

vertex-triangleInterior Intersection (P) (see Fig. 4, Fig. 5(a, b, d))
edgeInterior-edgeInterorCross Intersection (P) (Fig. 4, Fig. 5(a, b, c))
edge-triangleInterior Intersection (P) (see Fig. 5(d))
triangleInterior-triangleInterior Intersection (P) (see Fig. 4, Fig. 5(a, b, c, d))

It is possible that two triangles cross intersect in a line segment even when a triangle is on one side of the other triangle. In that case, it may be desirable to know which side of the other triangle is occupied. In Fig. 3(b), the triangle PQR (except QR which is in ABC ) is on the positive side of triangle ABC . So PQR does not intersect the interior of object of triangle ABC . We will use this concept in Section VI. Section VII concludes, followed by references in Section VIII.

It should be noted that the vertex-edge intersection encompasses vertex-vertex, vertex-edgeInterior intersection, whereas the vertex-triangle intersection encompasses vertexvertex, vertex-edgeInterior, and vertex-triangleInterior. Thus 1D JEPD cross intersection between ABC and PQR can be one of the three possibilities: (1) collinear along edges, (2) an edge of PQR lying in the plane of triangle ABC , or (3) triangles "pierce" through each other yielding an intersection segment.

## IV. The Overall Algorithm (Intersection Between Triangles)

In this section, we describe the overall structure of the triangle-triangle intersection. In Section IV.A, we develop sub-algorithms that support the main algorithm at its intermediate steps. In addition to existence or nonexistence of an intersection, this algorithm also supports other auxiliary computations, (e.g. classification of intersection and the calculation of 3D intersection points, segment or area) which are necessary for some applications.

## A. Description of the Overall Algorithm

The general structure of the overall triangle-triangle intersection algorithm is presented here. The description is in Python style so that it can be easily transported to programmable code. Here is the traditional approach to the algorithm, whereas our approach is presented in Section V.

Fig. 1. Disjoint triangles: Planes supporting the triangles may be crossing or coplanar. The triangles do not have anything in common.

(c) vertex_trianglelnterior

(b) vertex_edgelnterior

Fig. 2. Triangles intersect at a single point. The intersections between triangles ABC and PQR are JEPD (Jointly Exhaustive and Pairwise Distinct) cases of Single Point intersection between triangles. (a) vertex-vertex and (b) vertex-edgeInterior can occur in both cross and coplanar intersections. However, (c) vertextriangleInterior and (d) edgeInterior-edgeInterior intersection point can occur in cross intersection only.

Fig. 3. Triangles intersect in a line segment. (a) edge-edgeCollinear intersection can occur in both cross and coplanar intersections. However, (b) edge-triangleInterior and (c) triangleInteriortriangleInterior intersection segment occur in cross intersection only.

Fig. 4. Triangles intersect in an area. (a) One edge of triangle PQR and two edges AB and AC of triangle ABC intersect, vertex A is in the interior of PQR . (b) One edge of triangle PQR with three edges of $A B C$, and vertex $A$ in the interior of $P Q R$. The common area is bounded by three edges. The intersections vertex-triangleInterior, edge_triangle, edgeInterior-triangleInterior hold.

Fig. 5. Triangles intersect in an area (continued). The coplanar triangle intersections are bounded by four, five, and six edge segments. (a) Two edges of triangle $P Q R$ and two edges $A B$ and $A C$ of triangle $A B C$ intersect, vertex $A$ is in the interior of $P Q R$, vertex $R$ is in the interior of triangle $A B C$. The intersection area is bounded by four edges. (b) Two edges of triangle PQR and three edges of triangle ABC intersect; vertex C is in the interior of PQR . The intersection area is bounded by five edges. (c) Three edges of triangle PQR and three edges of triangle ABC intersect; every vertex of one triangle is outside the other triangle. The intersection area is bounded by six edges. (d) No edge of triangle PQR intersects any edge of triangle ABC ; vertices $\mathrm{P}, \mathrm{Q}, \mathrm{R}$ are in the interior of triangle ABC . The intersection area is the triangle PQR .

## boolean triTriInt(tr1 = ABC, $\operatorname{tr2}=P Q R$ )

Input: two triangles ABC and PQR
Output: Boolean value whether the triangles intersect or not.

Let ABC and PQR be two triangles. The triangles are represented with parametric vector equations where $u, v$ are
parameters for triangle ABC , and $\mathrm{s}, \mathrm{t}$ are parameters for triangle PQR .

$$
\begin{aligned}
& \mathrm{R}_{1}(u, v)=A+u U+v V \text { with } 0 \leq u, v, u+v \leq 1 \\
& \mathrm{R}_{2}(s, t)=P+s S+t T \text { with } 0 \leq s, t, s+t \leq 1
\end{aligned}
$$

where

$$
\begin{aligned}
& U=B-A, V=C-A, \text { are directions of the edges at A; } \\
& S=Q-P, T=R-P \text { are the directions of edges at } \mathrm{P} .
\end{aligned}
$$

Let $\mathrm{N}_{1}=\mathrm{UxV}, \mathrm{N}_{2}=$ SxT be the normals to planes supporting the triangles ABC and PQR .

```
if }\mp@subsup{\textrm{N}}{1}{}\mp@subsup{\textrm{XN}}{2}{}\not=0\mathrm{ // planes supporting triangles are not parallel
    if triTriCrossInt (tr1, tr2) // cross intersect the triangles
        return true
    else
        return false
    elseif }\mp@subsup{\textrm{N}}{1}{}\mp@subsup{\textrm{XN}}{2}{}=0,// triangles planes are parallel
        if AP}\cdot\mp@subsup{\textrm{N}}{1}{}=0,//the triangles are coplanar
            if triTriParInt (tr1, tr2)// implicit in Section V.
                return true
            else
                return false
        elseif AP• N
            no Intersection
            return false
        endif
endif
/*end of algorithm*/
```

Here, we give all the supporting algorithms for implementation and classification of all special case intersections in the main algorithm. There are three broad categories for intersections of triangles: zero dimensional (single point), one-dimensional (line segment), and two dimensional (area) intersection.

## A. 1 Single Point Intersection (0D).

We first analyze the vertices of the triangle PQR with respect to triangle $A B C$ to determine if a vertex $P$ or $Q$ or $R$ is common to the ABC triangle and conversely.

## vertex-triangleTest ( X, tri $=A B C$ )

Input: X is a vertex of one triangle and tri another triangle.
Output: boolean value determining whether X is a vertex, edgeInterior, triangleInterior point of the triangle.

To determine the relation of $\mathrm{X} \in\{\mathrm{P}, \mathrm{Q}, \mathrm{R}\}$ to the triangle ABC , we solve

$$
A+u U+v V=X \text { for } 0 \leq u, v, u+v \leq 1,
$$

Rearranging the equation, we get

$$
u U+v V=A X
$$

To eliminate one of the parameters $u$, $v$ to solve this, we dot product the equation with vectors $(\mathrm{UxV}) \mathrm{xU}$ and $(\mathrm{UxV}) \mathrm{xV}$. Let

$$
\gamma=\frac{A X \times(U \times V)}{(U \times V) \bullet(U \times V)}
$$

then $u=-\gamma \cdot V$ and $v=\gamma \cdot U$
if $0 \leq u, v, u+v \leq 1$,
return true // X of PQR , intersects the triangle ABC .
else
return false
/*end of algorithm*/
The vector $\frac{(U \times V)}{(U \times V) \bullet(U \times V)}$ is computed only once and used repeatedly. As a result $\gamma=\frac{A X \times(U \times V)}{(U \times V) \cdot(U \times V)}$ is calculated with one cross product, and $u, v$ are calculated with one dot product. The parameters $\mathrm{u}, \mathrm{v}$ naturally lend themselves to classification of intersections. Similarly, $\gamma^{\prime}=\frac{P X \times(S \times T)}{(S \times T) \bullet(S \times T)}$.

## A.2 Classification of Intersection.

In order to determine whether the vertex X of triangle PQR is a vertex of ABC , or on the edge of ABC , or an interior point of triangle ABC , no extra computational effort is required now. Logical tests are sufficient to establish the classification of this intersection. Since $0 \leq u, v, u+v \leq 1$, we can classify X relative to ABC in terms of the following predicates:
vertex $((\mathbf{u}, \mathbf{v}))$ : If $(u, v) \in\{(0,0),(0,1),(1,0)\}$, then $X$ is one of the vertices of ABC .
edgeInterior $((\mathrm{u}, \mathrm{v}))$ : If $(\mathrm{u}=0,0<\mathrm{v}<1)$ or $(\mathrm{v}=0,0<\mathrm{u}<$

1) or $(u+v=1,0<u<1)$ ), then $X$ is on an edge of $A B C$, excluding vertices.
triangleInterior $((\mathbf{u}, \mathbf{v}))$ : If $(0<u<1$ and $0<v<1$ and $0<$ $\mathrm{u}+\mathrm{v}<1$ ), X is an interior point (excluding boundary) of the triangle ABC .

Similarly, as above we can classify vertex X of triangle ABC as vertex, edgeInterior, or triangleInterior point of triangle $P Q R$. Single point intersection may result from cross intersection of edges as well. An edge point may be a vertex or an interior point of the edge.

## A. 3 The Edge-edge Single Point Intersection.

If two triangles cross intersect across an edge, the edge-toedge intersection results in a single point. The edge-edge cross intersection algorithm is presented below.

## edge_edgeCrossIntersection (edge1, edge2)

Let the two edges be AB and PQ . Then the edges are represented with equations

$$
\begin{aligned}
& \mathrm{X}=\mathrm{A}+\mathrm{u} \mathrm{U} \text { with } \mathrm{U}=\mathrm{B}-\mathrm{A}, 0 \leq \mathrm{u} \leq 1 \\
& \mathrm{X}=\mathrm{P}+\mathrm{s} \mathrm{~S} \text { with } \mathrm{S}=\mathrm{Q}-\mathrm{P}, 0 \leq \mathrm{s} \leq 1
\end{aligned}
$$

if $\mathrm{U} \times \mathrm{S} \bullet \mathrm{AP} \neq 0$, return false // non-coplanar lines elseif $U \times S=0$, return false // lines are parallel else $\mathrm{U} \times \mathrm{S} \neq 0$, // lines cross
$/ *$ solve for $u_{\mathrm{P}}, \mathrm{s}_{\mathrm{A}}$ values for the intersection point*/

$$
\begin{array}{r}
\mathrm{A}+\mathrm{u}_{\mathrm{P}} \mathrm{U}=\mathrm{P}+\mathrm{s}_{\mathrm{A}} \mathrm{~S} \\
\mathrm{u}_{\mathrm{P}}=\mathrm{S} \cdot \mathrm{PA} \times(\mathrm{U} \times \mathrm{S}) /(\mathrm{U} \times \mathrm{S} \cdot \mathrm{U} \times \mathrm{S}) \\
u_{P}=\frac{S \bullet P A \times(U \times S)}{(U \times S) \bullet(U \times S)}
\end{array}
$$

if ( $u_{P}<0$ ) or ( $u_{P}>1$ ), return false // no cross intersection,

$$
s_{A}=\frac{U \bullet A P \times(U \times S)}{(U \times S) \bullet(U \times S)}
$$

if $\left(\mathrm{s}_{\mathrm{A}}<0\right)$ or $\left(\mathrm{s}_{\mathrm{A}}>1\right)$, return false //no cross intersection,
else return true //there is edge-edge cross intersection. endif
/* end of algorithm*/

## A. 4 Composite Classification Of Single Point Intersection.

Let $A_{m}, \mathrm{P}_{\mathrm{m}}$, be the pair of bilinear parametric coordinates of the 3D intersection points $R_{1}\left(u_{m}, v_{m}\right)$ and $R_{2}\left(s_{m}, t_{m}\right)$ with respect to triangles $A B C$ and $P Q R$ respectively. When there is no confusion, we will refer to the points as $\mathrm{A}_{\mathrm{m}}$ and $\mathrm{P}_{\mathrm{m}}$ instead of 3 D points $\mathrm{R}_{1}\left(\mathrm{u}_{\mathrm{m}}, \mathrm{v}_{\mathrm{m}}\right)$ and $\mathrm{R}_{2}\left(\mathrm{~s}_{\mathrm{m}}, \mathrm{t}_{\mathrm{m}}\right)$. From vertex-triangle intersection (Section 3) we have
$P_{m}$ is a vertex of PQR, and $A_{m}=\left(u_{m}, v_{m}\right)$, where $u_{m}$ and $v_{m}$ are $u_{m}=-\gamma \cdot V, v_{m}=\gamma \cdot U$ or $A_{m}$ is a vertex of $A B C$, and $P_{m}=$ $\left(\mathrm{s}_{\mathrm{m}}, \mathrm{t}_{\mathrm{m}}\right)$, where $\mathrm{s}_{\mathrm{m}}$ and $\mathrm{t}_{\mathrm{m}}$ ) are $\mathrm{s}_{\mathrm{m}}=-\gamma^{\prime} \cdot \mathrm{T}, \mathrm{t}_{\mathrm{m}}=\gamma^{\prime} \cdot \mathrm{S}$.

From edge-edge intersection (Section B.3) we have

$$
\begin{aligned}
& \mathrm{A}_{\mathrm{m}}=\left(0, u_{P}\right) \text { or }\left(u_{P}, 0\right) \text { or }\left(u_{P}, 1-u_{P}\right) \text { or }\left(1-u_{P}, u_{P}\right) \\
& P_{m}=\left(0, s_{A}\right) \text { or }\left(s_{A}, 0\right) \text { or }\left(s_{A}, 1-s_{A}\right) \text { or }\left(1-s_{A}, s_{A}\right)
\end{aligned}
$$

If ( $u_{P}=0$ or 1 ) and $\left(s_{A}=0\right.$ or 1$)$, it is vertex-vertex intersection. If $\left(u_{P}=0\right.$ or 1$)$ and $\operatorname{not}\left(s_{A}=0\right.$ or 1$)$, it is vertexedgeInterior intersection. If not $\left(\mathrm{u}_{\mathrm{P}}=0\right.$ or 1$)$ and ( $\mathrm{s}_{\mathrm{A}}=0$ or 1 ), it is edgeInterior-vertex intersection. If not ( $u_{P}=0$ or 1 ) and not ( $\mathrm{s}_{\mathrm{A}}=0$ or 1 ), it is edgeInterior-edgeInterior intersection. This completes the discussion of single point intersection classification and parameters for the corresponding 3D points.

## B. Line Intersection (1D)

Besides edge-edge cross intersection, the edge-edge collinear intersection is a possibility, independent of crossing
or coplanar triangles. In this section, we discuss algorithms that result in a segment (1D) intersection; see Fig. 3.

## B. 1 Intersection Algorithm And Parametric Coordinates.

Here we derive an edge-edgeCollinear intersection algorithm. This algorithm is seamlessly applicable to both cross-intersecting and coplanar triangles. The following algorithm implements intersection of edges of the triangles ABC and PQR .

## boolean edge-edgeCollinearTest (edge1, edge2)

input: two line segments
output: true if the segments have a common intersection, else false. First we compute the linear parameter coordinates $u_{P}, u_{Q}, s_{A}, s_{B}$ for intersection of $X=A+u(B-A)$, for $X=P$, Q and $\mathrm{X}=\mathrm{P}+\mathrm{s}(\mathrm{Q}-\mathrm{P})$, for $\mathrm{X}=\mathrm{A}, \mathrm{B}$. Similarly, we can compute the intersection of other edges of triangle ABC with any edge of triangle PQR . Then we update the parameters for the common segment. This algorithm is standard, straightforward and is omitted for the sake of limited space.

## B. 2 Classification of Edge-edge Intersection

Now we have the linear coordinates for intersection points $u_{P}, u_{Q}$ and $s_{A}, s_{B}$. We map the linear parameters for intersection points to bilinear parameter coordinates ( $u, v$ ) and $(s, t)$. If $u_{P}, u_{Q}$ are known along an edge and the edge is $A B$, let $u_{m}=u_{P}, u_{M}=u_{Q}, v_{m}=0, v_{M}=0$;

Similarly for $A C$, let $v_{m}=u_{P}, v_{M}=u_{Q}, u_{m}=0, u_{M}=0$; and for BC, let $u_{m}=u_{P}, u_{M}=u_{Q}, v_{m}=1-u_{P}, v_{M}=1-u_{Q}$;

Thus ABC triangle bilinear coordinates for the intersection points are:

$$
A_{m}=\left(u_{m}, v_{m}\right), A_{M}=\left(u_{M}, v_{M}\right)
$$

where $\mathrm{v}_{\mathrm{m}}=\mathrm{v}_{\mathrm{M}}=0$ or $\mathrm{u}_{\mathrm{m}}=\mathrm{u}_{\mathrm{M}}=0$ or $\mathrm{u}_{\mathrm{m}}+\mathrm{v}_{\mathrm{m}}=\mathrm{u}_{\mathrm{M}}+\mathrm{v}_{\mathrm{M}}=1$.
Similarly for the triangle PQR, the linear coordinates $\mathrm{s}_{\mathrm{A}}, \mathrm{s}_{\mathrm{B}}$ of intersection translate into bilinear coordinates

$$
\mathrm{P}_{\mathrm{m}}=\left(\mathrm{s}_{\mathrm{m}}, \mathrm{t}_{\mathrm{m}}\right), \mathrm{P}_{\mathrm{M}}=\left(\mathrm{s}_{\mathrm{M}}, \mathrm{t}_{\mathrm{M}}\right)
$$

where $\mathrm{t}_{\mathrm{m}}=\mathrm{t}_{\mathrm{M}}=0$ or $\mathrm{s}_{\mathrm{m}}=\mathrm{s}_{\mathrm{M}}=0$ or $\mathrm{s}_{\mathrm{m}}+\mathrm{t}_{\mathrm{m}}=\mathrm{s}_{\mathrm{M}}+\mathrm{t}_{\mathrm{M}}=1$.
Now we have the bilinear parametric coordinates $u, v, s, t$ for the intersection segment. The common 3D segment is denoted by $\left[\mathrm{R}_{1}\left(\mathrm{~A}_{m}\right), \mathrm{R}_{1}\left(\mathrm{~A}_{\mathrm{M}}\right)\right]$ which is $\left[\mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{m}}\right), \mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{M}}\right)\right]$ or $\left[\mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{M}}\right), \mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{m}}\right)\right]$. It is possible that the intersection segment is equal to both edges, or it overlaps both edges, or it is entirely contained in one edge. Since the intersection is a part of the edges, it cannot properly contain any edge.

## B.3. Composite Classification of Line Intersection.

For collinear edge intersection $\mathrm{A}_{\mathrm{m}}, \mathrm{A}_{\mathrm{M}}$ are normally distinct and similarly $\mathrm{P}_{\mathrm{m}}, \mathrm{P}_{\mathrm{M}}$ may be distinct. Though the intersection
segment is given by $\left[\mathrm{R}_{1}\left(\mathrm{~A}_{\mathrm{m}}\right), \mathrm{R}_{1}\left(\mathrm{~A}_{\mathrm{M}}\right)\right]=\left[\mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{m}}\right), \mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{M}}\right)\right)$ or $\left[R_{1}\left(A_{m}\right), R_{1}\left(A_{M}\right)\right]=\left[R_{2}\left(P_{m}\right), R_{2}\left(P_{M}\right)\right]$, it is not necessary that parameter coordinates $\left[\mathrm{A}_{\mathrm{m}}, \mathrm{A}_{\mathrm{M}}\right]=\left[\mathrm{P}_{\mathrm{m}}, \mathrm{P}_{\mathrm{M}}\right]$ or $\left[\mathrm{A}_{\mathrm{m}}, \mathrm{A}_{\mathrm{M}}\right]=\left[\mathrm{P}_{\mathrm{M}}\right.$, $\left.P_{m}\right]$. The predicate for edge-edge collinear intersection segment becomes:
edge-edgeCollinear (edge1, edge2) $=$ edge $\left(\left[\mathrm{A}_{\mathrm{m}}, \mathrm{A}_{\mathrm{M}}\right]\right)$ and edge $\left(\left[\mathrm{P}_{\mathrm{m}}, \mathrm{P}_{\mathrm{M}}\right]\right)$ and $\left[\mathrm{R}_{1}\left(\mathrm{~A}_{\mathrm{m}}\right), \mathrm{R}_{1}\left(\mathrm{~A}_{\mathrm{M}}\right)\right]==\left[\mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{m}}\right), \mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{M}}\right)\right]$ or $\left[R_{1}\left(A_{m}\right), R_{1}\left(A_{M}\right)\right]==\left[R_{2}\left(\mathrm{P}_{\mathrm{M}}\right), \mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{m}}\right)\right]$

Also it may be noted that for a cross intersection triangle, an edge-triangleInterior intersection may result in a segment intersection (Fig. 3(b)). For cross intersecting planes we have (cf. 3.A for vertex to triangle intersection and [7]) .
edge-triangle (edge, triangle) $=$ edge $\left(\left[\mathrm{A}_{\mathrm{m}}, \mathrm{A}_{\mathrm{M}}\right]\right)$ and triangle $\left(\left[\mathrm{P}_{\mathrm{m}}, \mathrm{P}_{\mathrm{M}}\right]\right)$ and $\left[\mathrm{R}_{1}\left(\mathrm{~A}_{\mathrm{m}}\right), \mathrm{R}_{1}\left(\mathrm{~A}_{\mathrm{M}}\right)\right]==\left[\mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{m}}\right), \mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{M}}\right)\right]$ or $\left[R_{1}\left(A_{m}\right), R_{1}\left(A_{M}\right)\right]==\left[R_{2}\left(\mathrm{P}_{\mathrm{M}}\right), \mathrm{R}_{2}\left(\mathrm{P}_{\mathrm{m}}\right)\right]$

This completes the discussion of segment intersection (1D), classification, 3D points for both cross and coplanar triangle intersections.

## V. Area Intersection

For coplanar triangles, there may be no intersection (Fig. 1), a single point (Fig. 2(a, b)), a segment (Fig. 3(a)) or an area (Fig. 4, Fig. 5(a, b, c)), including one triangle contained in another, (Fig. 5(d)). An area can result from two edges of one triangle and one, two, or three edges of another triangle, or three edges from both triangles creating a star shaped figure. The resulting area is bounded by $3,4,5$, or 6 edges. All other configurations are homeomorphic to the figures presented in this paper. For qualitative spatial reasoning, in some cases (when the knowledge of cross intersection is insufficient), we resort to coplanar intersection to distinguish the externally or tangentially connected objects.

## A. General Purpose Algorithm

If a vertex of PQR is in the interior of ABC (or the converse is true), then an area intersection occurs, (Fig. 4(a, b), Fig. 5(a, $\mathrm{b}, \mathrm{d})$ ). If no two edges intersect and vertex_triangleInterior (vertex, triangle $=\operatorname{tr} 2$ ) for every vertex of a triangle tr1, then the triangle tr1 is contained in tr2 and conversely. If no edgeedge intersection takes place and no vertex of one triangle is inside the other triangle (or the converse is true), then they are disjoint.

Although this algorithm may look simple, it is a new approach compared to previous approaches cited in the background section. The existing methods may use alternate edge-oriented techniques to determine the area of intersection; however, those will be limited [11]. Our algorithm is more comprehensive and analytically rigorous; it is implicitly capable of handling any specific type of intersection simultaneously, which may be a single point, a segment or an area.

## The Algorithm: A Novel Approach

## boolean triTriIntersection (tr1 = ABC, $\operatorname{tr2}=P Q R$ )

The triangles ABC and PQR are
$\mathrm{X}=\mathrm{A}+\mathrm{u} \mathrm{U}+\mathrm{v} \mathrm{V}$ with $\mathrm{U}=\mathrm{B}-\mathrm{A}, \mathrm{V}=\mathrm{C}-\mathrm{A}, 0 \leq \mathrm{u}, \mathrm{v}, \mathrm{u}+\mathrm{v}$ $\leq 1$
$\mathrm{X}=\mathrm{P}+\mathrm{s} \mathrm{S}+\mathrm{t} \mathrm{T}$ with $\mathrm{S}=\mathrm{Q}-\mathrm{P}, \mathrm{T}=\mathrm{R}-\mathrm{P}, 0 \leq \mathrm{s}, \mathrm{t}, \mathrm{s}+\mathrm{t} \leq 1$
The general set up for detecting intersections is to solve the equation

$$
A+u U+v V=P+s S+t T
$$

for $\mathrm{u}, \mathrm{v}, \mathrm{s}, \mathrm{t}$. If a solution exists satisfying the constraints $0 \leq$ $\mathrm{u}, \mathrm{v}, \mathrm{u}+\mathrm{v}, \mathrm{s}, \mathrm{t}, \mathrm{s}+\mathrm{t} \leq 1$, then there is an intersection, else there is no intersection.

Rearranging the equation, we have

$$
\begin{equation*}
u U+v V=A P+s S+t T \tag{1}
\end{equation*}
$$

For simplicity in solving (1), we use the following notation.
Let $\alpha, \beta, \gamma$ be vectors and $\delta$ be a positive real number. Then for triangle ABC , let $\mathrm{AP}=\mathrm{P}-\mathrm{A}$ be a vector, $\delta=$ $(\mathrm{U} \times \mathrm{V}) \bullet(\mathrm{U} \times \mathrm{V})$,

$$
\alpha=\frac{S \times(U \times V)}{\delta}, \beta=\frac{T \times(U \times V)}{\delta}, \gamma=\frac{A P \times(U \times V)}{\delta}
$$

Similarly, let $\alpha^{\prime}, \beta^{\prime}, \gamma^{\prime}$ be vectors and $d^{\prime}$ be a positive real number. Then for triangle PQR , let

$$
\begin{aligned}
& \mathrm{PA}=\mathrm{A}-\mathrm{P} \text { be a vector, } \delta^{\prime}=(\mathrm{S} \times \mathrm{T}) \bullet(\mathrm{S} \times \mathrm{T}) \\
& \alpha^{\prime}=\frac{U \times(S \times T)}{\delta}, \beta^{\prime}=\frac{V \times(S \times T)}{\delta}, \gamma^{\prime}=\frac{P A \times(S \times T)}{\delta} .
\end{aligned}
$$

For intersection between triangles ABC and PQR , on dotting equation (1) with $(\mathrm{U} \times \mathrm{V}) \times \mathrm{U}$ and $(\mathrm{U} \times \mathrm{V}) \times \mathrm{V}$, we quickly get

$$
\begin{aligned}
& u=-(\gamma \cdot V+s \alpha \cdot V+t \beta \cdot V) \\
& v=\gamma \cdot U+s \alpha \cdot U+t \beta \cdot U
\end{aligned}
$$

Adding the two equations,

$$
\mathrm{u}+\mathrm{v}=\gamma \cdot(\mathrm{U}-\mathrm{V})+\mathrm{s} \alpha \cdot(\mathrm{U}-\mathrm{V})+\mathrm{t} \beta \cdot(\mathrm{U}-\mathrm{V})
$$

In order that $0 \leq u, v, u+v \leq 1$, we get the following inequalities for possible range of values for $s$ and $t$
(a) $-\gamma \cdot \mathrm{U} \leq \alpha \cdot \mathrm{U}$ s $+\beta \cdot \mathrm{Ut} \leq 1-\gamma \cdot \mathrm{U}$
(b) $-1-\gamma \cdot \mathrm{V} \leq \alpha \cdot \mathrm{V} \mathrm{s}+\beta \cdot \mathrm{Vt} \leq-\gamma \cdot \mathrm{V}$
(c) $-\gamma \cdot(\mathrm{U}-\mathrm{V}) \leq \alpha \bullet(\mathrm{U}-\mathrm{V}) \mathrm{s}+\beta \cdot(\mathrm{U}-\mathrm{V}) \mathrm{t} \leq 1-\gamma \bullet(\mathrm{U}-\mathrm{V})$

These linear inequalities (a)-(c) are of the form

$$
m \leq a x+b y \leq n
$$

The solution to this system of inequalities is derived at the end of this section. We apply the results of the algorithms here in solving (a) - (c).

If we solve_x $(-\gamma \cdot \mathrm{U}, \alpha \cdot \mathrm{U}, \beta \cdot \mathrm{U}, 1-\gamma \cdot \mathrm{U},-\gamma \cdot \mathrm{V}, \alpha \cdot \mathrm{V}, \beta \cdot \mathrm{V}$, $\left.1-\gamma \cdot \mathrm{V}, \mathrm{x}_{\mathrm{m}}, \mathrm{x}_{\mathrm{M}}\right)$

$$
\mathrm{s}_{\mathrm{m}}=\max \left(0, \mathrm{x}_{\mathrm{m}}\right), \mathrm{s}_{\mathrm{M}}=\min \left(1, \mathrm{x}_{\mathrm{M}}\right)
$$

If we solve_x $(-\gamma \cdot U, \alpha \cdot U, \beta \cdot U, 1-\gamma \cdot U,-\gamma \cdot(U-V), \alpha \cdot(U$ $\left.-\mathrm{V}), \beta \cdot(\mathrm{U}-\mathrm{V}), 1-\gamma \cdot(\mathrm{U}-\mathrm{V}), \mathrm{x}_{\mathrm{m}}, \mathrm{x}_{\mathrm{M}}\right)$

$$
\mathrm{s}_{\mathrm{m}}=\max \left(\mathrm{s}_{\mathrm{m}}, \mathrm{x}_{\mathrm{m}}\right), \mathrm{s}_{\mathrm{M}}=\min \left(\mathrm{x}_{\mathrm{M}}, \mathrm{~s}_{\mathrm{M}}\right)
$$

If we solve_x $(-1-\gamma \cdot V, \alpha \cdot V, \beta \cdot V,-\gamma \cdot V,-\gamma \cdot(U-V)$, $\left.\alpha \cdot(U-V), \beta \cdot(U-V), 1-\gamma \cdot(U-V), x_{m}, x_{M}\right)$

$$
\mathrm{s}_{\mathrm{m}}=\max \left(\mathrm{s}_{\mathrm{m}}, \mathrm{x}_{\mathrm{m}}\right), \mathrm{s}_{\mathrm{M}}=\min \left(\mathrm{x}_{\mathrm{M}}, \mathrm{~s}_{\mathrm{M}}\right)
$$

$$
\text { if } \mathrm{s}_{\mathrm{m}}>\mathrm{s}_{\mathrm{M}}
$$

return false
else

$$
\mathrm{t}_{\mathrm{M}}=0 ; \mathrm{t}_{\mathrm{m}}=1
$$

for $\mathrm{s} \in\left[\mathrm{s}_{\mathrm{m}}, \mathrm{s}_{\mathrm{M}}\right] / /$ we solve the inequalities for t
if solve_y $(-\gamma \cdot \mathrm{U}, \alpha \cdot \mathrm{U}, \beta \cdot \mathrm{U}, 1-\gamma \cdot \mathrm{U},-\gamma \cdot \mathrm{V}, \square \alpha \cdot \mathrm{V}$,
$\beta \cdot \mathrm{V}, 1-\gamma \cdot \mathrm{V}, \mathrm{s}, \mathrm{y}_{\mathrm{m}}$, ум $)$
$\mathrm{t}_{\mathrm{m}}(\mathrm{s})=\max \left(0, \mathrm{y}_{\mathrm{m}}\right), \mathrm{t}_{\mathrm{M}}(\mathrm{s})=\min \left(1, \mathrm{y}_{\mathrm{M}}\right)$,
$\mathrm{t}_{\mathrm{m}}=\min \left(\mathrm{t}_{\mathrm{m}}(\mathrm{s}), \mathrm{t}_{\mathrm{m}}\right), \mathrm{t}_{\mathrm{M}}=\max \left(\mathrm{t}_{\mathrm{M}}(\mathrm{s}), \mathrm{t}_{\mathrm{M}}\right) / /$ extent of overall $t$ values

$$
\text { if } \mathrm{t}_{\mathrm{m}}(\mathrm{~s})>\mathrm{t}_{\mathrm{M}}(\mathrm{~s})
$$

Return false
else

$$
\mathrm{t}_{\mathrm{m}}(\mathrm{~s}) \leq \mathrm{t} \leq \mathrm{t}_{\mathrm{M}}(\mathrm{~s})
$$ return true

/* end of algorithm */
We first solved the three inequalities pairwise for a range of values for s , so that $\mathrm{s}_{\mathrm{m}} \leq \mathrm{s} \leq \mathrm{s}_{\mathrm{M}}$ holds good simultaneously with three inequalities. Then from this range of $s$ values, we solved for $t$ as a function of $s$ such that $t_{m}(s) \leq s \leq t_{M}(s)$, and overall $\mathrm{t}_{\mathrm{m}} \leq \mathrm{t}_{\mathrm{M}}$. If it succeeds, it ensures that there is a solution. Similarly, we determine for u-parameter and vparameter values in terms of $u$ to obtain the area enclosed by the two triangles. This algorithm detects whether coplanar triangles intersect, and we classify the intersection as in Section V.B. Here we describe the two algorithms we applied in the general-purpose algorithm. An auxiliary algorithm solves inequalities of the form

$$
\begin{aligned}
& m \leq a x+b y \leq n, \text { and } \\
& M \leq A x+B y \leq N
\end{aligned}
$$

The brute force method for solving these inequalities may lead to an erroneous solution as shown in the following example. The general elimination of variables principle that works well for equations does not directly translate into solving inequalities. Such approach gives an inconsistent solution to the two inequalities
(a) $-1 \leq x+y \leq 1$ and
(b) $-1 \leq x-y \leq 1$

Since $-1 \leq \mathrm{x}-\mathrm{y} \leq 1$ is equivalent to $-1 \leq-\mathrm{x}+\mathrm{y} \leq 1$, adding and subtracting the two inequalities (a) and (b), yields an inaccurate answer $-1 \leq \mathrm{x} \leq 1$, and $-1 \leq \mathrm{y} \leq 1$ which is the area enclosed by dotted boundary in Fig. 6. But the accurate solution is in the shaded area in Fig. 6, which is $|x| \leq 1$, and $|y|$ $\leq(1-|x|)$.

Thus to accurately solve these two inequalities $-1 \leq x+y \leq$ 1 and $-1 \leq x-y \leq 1$, we first solve these for one variable $x$, then use this variable value to solve for the other variable y as $-(1-|x|) \leq y \leq(1-|x|)$.

First, we solve two most general inequalities

$$
\begin{gather*}
\mathrm{m} \leq \mathrm{ax}+\mathrm{by} \leq \mathrm{n}  \tag{1}\\
\mathrm{M} \leq \mathrm{Ax}+\mathrm{By} \leq \mathrm{N} \tag{2}
\end{gather*}
$$

The following algorithm determines $\mathrm{x}_{\mathrm{m}}, \mathrm{x}_{\mathrm{M}}$ such that for each $x$ in $\left[x_{m}, x_{M}\right]$, the inequalities hold.

Fig. 6. Solution to a pair of inequalities: $-1 \leq x+y \leq 1$ and $-1 \leq$ $x-y \leq 1$. Using brute force method of elimination of variables yields the area enclosed by the dotted boundary, but the accurate solution is enclosed by the shaded area.

## boolean solve_x (m, $\left.a, b, n, M, A, B, N, x_{m}, x_{M}\right)$

If a solution is found, it returns true, else it returns false. First assume $b$ and $B$ are non-negative. If not, multiply them by -1 to make them non-negative. Multiplying (1) by B and (2) by b, subtraction leads to

$$
(\mathrm{mB}-\mathrm{Mb}) \leq(\mathrm{aB}-\mathrm{Ab}) \mathrm{x} \leq(\mathrm{nB}-\mathrm{Nb}),
$$

which yields the range $\left[\mathbf{x}_{\mathbf{m}}, \mathbf{x}_{\mathbf{M}}\right]$ for x values in addition to true or false value for the algorithm.

Now once $x_{m}, x_{M}$ have been determined, for each $x$ in $\left[x_{m}\right.$, $\left.x_{M}\right]$ in the inequalities, we determine the range $\left[y_{m}(x), y_{M}(x)\right.$ ] for y . That is, after the range $\left[\mathrm{x}_{\mathrm{m}}, \mathrm{x}_{\mathrm{M}}\right.$ ] is determined, only then for each x in $\left[\mathrm{x}_{\mathrm{m}}, \mathrm{x}_{\mathrm{M}}\right.$ ], the range for y is determined; in other words, y is a function of x .

$$
\text { boolean solve_y (m, a, b, n, M, A, B, N, x, } \left.y_{m}, y_{m}\right)
$$

Given that $\mathrm{x}_{\mathrm{m}} \leq \mathrm{x} \leq \mathrm{x}_{\mathrm{M}}$ are known, it solves the inequalities for $y_{m}, y_{M}$. In the process, it may update the values of $x_{m}, x_{M}$ as needed.

If a solution is found, it returns true else it returns false. Now for $\mathrm{x}_{\mathrm{m}} \leq \mathrm{x} \leq \mathrm{x}_{\mathrm{M}}$, the inequalities become

$$
\begin{aligned}
& m-a x \leq b y \leq n-a x \text { and } \\
& M-A x \leq B y \leq N-A x .
\end{aligned}
$$

These inequalities give the range $\left[y_{m}(x), y_{M}(x)\right]$ of values for $y$ as function of $x$.

This completes the general-purpose algorithm discussion for determining the triangle-triangle intersection algorithm completely.

## B. Composite classification for area intersection

In this section, we summarize the algorithms in Section V.A. The equations of the triangles ABC and PQR are

$$
\begin{aligned}
& \mathrm{R}_{1}(\mathrm{u}, \mathrm{v})=\mathrm{A}+\mathrm{u} \mathrm{U}+\mathrm{v} \mathrm{~V} \\
& \quad \text { where } \mathrm{U}=\mathrm{B}-\mathrm{A}, \mathrm{~V}=\mathrm{C}-\mathrm{A}, 0 \leq \mathrm{u}, \mathrm{v}, \mathrm{u}+\mathrm{v} \leq 1 \\
& \mathrm{R}_{2}(\mathrm{~s}, \mathrm{t})=\mathrm{P}+\mathrm{s} \mathrm{~S}+\mathrm{t} T, \\
& \quad \text { where } \mathrm{S}=\mathrm{Q}-\mathrm{P}, \mathrm{~T}=\mathrm{R}-\mathrm{P}, 0 \leq \mathrm{s}, \mathrm{t}, \mathrm{~s}+\mathrm{t} \leq 1
\end{aligned}
$$

These equations are independent of whether they are supported by crossing planes or coplanar planes. The crossintersecting triangles discussion is well researched, see Section II. Here we consider the general case, including crossing or coplanar triangles. In this case, the intersection may be an area in addition to a possible single point and a line segment. We first determined $\left[s_{m}, s_{M}\right]$ the range of $s$ values, then used the range on $s$ to solve for $\left[\mathrm{t}_{\mathrm{m}}(\mathrm{s}), \mathrm{t}_{\mathrm{M}}(\mathrm{s})\right]$, the range of $t$. If such a solution exists, it is ensured that the two triangles intersect, which is sufficient for some qualitative spatial reasoning applications. The uv values can be similarly derived for the triangle $A B C$ (e.g., first $u_{m}, u_{M}$ then $\left.v_{m}(u), v_{M}(u)\right)$. This algorithm may be used with any application (e.g., qualitative spatial reasoning, surface modeling, image processing etc.).

As described in Section III, an intersection can arise from crossing or coplanar triangles. For example, vertex-vertex or edge-edge intersection can occur regardless of triangles being coplanar or crossing. The algorithm determines whether intersection exists or not (i.e., it returns true or false). If true, the parameter coordinates of intersection are readily available. We can derive all the auxiliary information from the parametric coordinates; only logical tests are sufficient for classification of the intersections. It is not the intent of this algorithm to determine whether the triangles are crossing or coplanar.

This can be quickly determined as follows: if $\mathrm{U} \times \mathrm{V} \cdot \mathrm{S} \times \mathrm{T} \neq 0$, then triangles cross, else triangle planes are parallel. If $\mathrm{AP} \cdot \mathrm{U} \times \mathrm{V}=0$ or $\mathrm{AP} \cdot \mathrm{S} \times \mathrm{T}=0$, then the triangles are coplanar. The bilinear parameter coordinates are denoted by $A_{m}=\left(u_{m}\right.$, $\left.\mathrm{v}_{\mathrm{m}}\right), \mathrm{A}_{\mathrm{M}}=\left(\mathrm{u}_{\mathrm{M}}, \mathrm{v}_{\mathrm{M}}\right), \mathrm{P}_{\mathrm{m}}=\left(\mathrm{s}_{\mathrm{m}}, \mathrm{t}_{\mathrm{m}}\right), \mathrm{P}_{\mathrm{M}}=\left(\mathrm{s}_{\mathrm{M}}, \mathrm{t}_{\mathrm{M}}\right)$. The intersection points can be differentiated as follows.

If the algorithm returns false,
No Intersection

```
Elseif \(\left(\mathrm{A}_{\mathrm{m}}=\mathrm{A}_{\mathrm{M}}\right)\) or \(\left(\mathrm{P}_{\mathrm{m}}=\mathrm{P}_{\mathrm{M}}\right)\)
    Single Point Intersection
Elseif ( \(\mathrm{s}_{\mathrm{m}}=\mathrm{s}_{\mathrm{M}}\) or \(\mathrm{t}_{\mathrm{m}}=\mathrm{t}_{\mathrm{M}}\) or \(\mathrm{u}_{\mathrm{m}}=\mathrm{u}_{\mathrm{M}}\) or \(\mathrm{v}_{\mathrm{m}}=\mathrm{v}_{\mathrm{M}}\) )
```

    Line segment intersection common to two triangles
    Else

Area Intersection common to two triangles.
This will implicitly cover the case when a triangle is inside the other triangle as well. If triangles do not intersect, then the triangles are declared disjoint. This completes the discussion of overall intersection between triangles.

## VI. Application to Qualitative Spatial Reasoning

Qualitative Spatial Reasoning relies on intersections between objects whose boundaries are triangulated. The spatial relations are determined by the 9 -Intersection/4Intersection model [9, 10]. That is, for any pair of objects A and B, the interior-interior intersection predicate, $\operatorname{IntInt}(\mathrm{A}, \mathrm{B})$, has true or false value depending on whether the interior of A and the interior of B intersect without regard to precise intersection. Similarly $\operatorname{IntBnd}(A, B)$ represents the truth value for the intersection of the interior of $A$ and the boundary of $B$, and $\operatorname{BndBnd}(\mathrm{A}, \mathrm{B})$ represents the predicate for the intersection of the boundaries of A and B . These four qualitative spatial reasoning predicates are sufficient to define the RCC8 spatial relations (see Table 1).

In the application VRCC-3D+, the boundary of an object is already triangulated; that is, we will need to intersect pairs of only triangles. To reduce the computational complexity, the algorithm uses axis aligned bounding boxes (AABB) to determine the closest triangles that may possibly intersect. For example, for objects A and B , if bounding boxes for triangles of A are disjoint from bounding boxes for triangles of B , either $A$ is contained in $B$ (IntInt, BndInt is true) or $B$ is contained in A (IntInt, IntBnd is true) or A is disjoint from B. The test for such containment of objects can be designed by casting an infinite ray through the centroid of $A$. If the ray intersects $B$ an odd number of times, then $B$ is contained in $A$. Similarly, the test can be made if $A$ is contained in $B$. If $A$ is not contained in B and B is not contained in A , then A and B are disjoint (i.e., $\operatorname{IntInt}(\mathrm{A}, \mathrm{B}), \operatorname{IntBnd}(\mathrm{A}, \mathrm{B}), \operatorname{BndInt}(\mathrm{A}, \mathrm{B})$, and BndBnd(A, B) are all false).

If the triangles cross intersect (e.g., triangleInteriortriangleInterior is true), then IntInt, IntBnd, BndInt, BndBnd will be true. However if the triangles are coplanar and intersect, only $\operatorname{BndBnd}(A, B)$ is true and $\operatorname{IntInt}(A, B)$, $\operatorname{IntBnd}(A, B), \operatorname{BndInt}(A, B)$ are false for the objects; otherwise, $\operatorname{BndBnd}(\mathrm{A}, \mathrm{B})$ is also false.

It is possible that two triangles cross intersect in a line segment even when a triangle is on one side of the other
triangle, so edgeInterior-triangleInterior is true. In that case, it may be desirable to know which side of the other triangle is occupied. In Fig. 3(b), the triangle PQR is on the positive side of triangle ABC . For example, if trianglel of object A cross intersects the negative side of triangle2 of object B , then $\operatorname{BndInt}(\mathrm{A}, \mathrm{B})$ is true.

Table 2 enumerates the outcome for triangle-triangle intersection with respect to 3D objects. This is a characterization of the intersection predicates, which subsequently can be used to resolve the eight RCC8 relations. Here we assume all normals are oriented towards the outside of the object. Each characterization in Table 2 describes when the associated predicate is true. If the truth test fails, then other triangles need to be tested. If no pair of triangles results in a true value, then the result is false.

TABLE I.
RCC8 RELATIONS AND INTERSECTION PREDICATES, ONLY SHADED ENTRIES ARE NECESSARY.

| RCC8 |  |  |  | IntInt |
| ---: | :---: | :---: | :---: | :---: |
| BndBnd |  | IntBnd |  | BndInt |
| DC | F | F | F | F |
| EC | F | T | F | F |
| PO | T | T | T | T |
| EQ | T | T | F | F |
| TPP | T | T | F | T |
| NTPP | T | F | F | T |
| TPPc | T | T | T | F |
| NTPPc | T | F | T | F |

TABLE II.
Characterization of intersection predicates

| IntInt | At least one pair of triangles cross intersects (triangleInterior- <br> triangleInterior) Or an object is contained in the other. |
| :--- | :--- |
| BndBnd | At least one pair of triangles (cross or coplanar) intersects. |
| BndInt | At least one pair tr1 and tr2 intersect, at least one vertex of tr1 <br> is on the negative side of triangles of object 2. Or object 1 is <br> contained inside object2, i.e. every vertex of object1 is on the <br> negative side of triangles of object 2. |
| IntBnd | At least one pair tr1 and tr2 intersect, at least one vertex of tr2 <br> is on the negative side of triangles of object 1. Or object 2 is <br> contained inside object1, i.e. every vertex of object2 is on the <br> negative side of triangles of object 1. |

This characterizes the intersection predicates, which help in resolving the RCC 8 relations.

## VII. Conclusion

For the 9-Intersection model used in qualitative spatial reasoning, triangle-triangle intersection plays a prominent role. Herein we presented a complete framework for determining and characterizing the intersection of geometric objects. In contrast to other algorithms, our approach is a general technique to detect any type of intersection. It creates classifications by applying logical tests rather than computational arithmetic tests.

Thus, our algorithm not only detects whether or not an intersection exists, but also classifies intersections as a single
point, a line segment, or an area. The algorithm provides more information than required by spatial reasoning systems. Consequently, we hope the new ideas and additional information including classification of 3D intersection presented herein will be useful in other related applications.
